=== All integration tests completed ===
```

PHASE-V:

Q5.1: To implement pes checkout <branch>, the system must update .pes/HEAD to point to the new branch ref, retrieve the commit hash from that ref, and walk its tree object. The working directory must then be updated to match the blobs in that tree. This is complex because it requires safely deleting files not in the new tree and overwriting others without losing uncommitted user data.

Q5.2: A "dirty" directory is detected by comparing the current file hashes in the working directory against the hashes in the .pes/index. If they differ, the file has unstaged changes. If the file also

differs between the current branch and the target branch, checkout must refuse to prevent overwriting those changes.

Q5.3: In a "Detached HEAD" state, commits are created normally but are not linked to a branch reference. If the user checks out another branch, these floating commits become "dangling" and unreachable. A user could recover them by finding the commit hash in the object store and manually creating a new branch ref for it.

PHASE-VI

Q6.1: A mark-and-sweep algorithm is used. Starting from all refs in .pes/refs/heads/, the system "marks" all reachable commits, trees, and blobs using a hash set. For 100,000 commits, it would need to visit every unique object in that history (likely several hundred thousand). Any object in .pes/objects/ not in the "marked" set is deleted.

Q6.2: Concurrent GC is dangerous because a commit operation might calculate a hash and prepare to reference an object that GC just identified as "unreachable." GC could delete a new blob before the commit points to it. Real Git avoids this by only deleting unreachable objects older than a certain age (grace period).
